

# The Stable Matching Problem

Week 6 AI Inspire Winter 2020

# Tentative schedule of remaining sessions

— — —

- 1) Week 6 (Today)  $\Rightarrow$  Stable Matching
- 2) Week 7  $\Rightarrow$  P vs NP
- 3) Week 8  $\Rightarrow$  P vs NP part 2
- 4) Week 9  $\Rightarrow$  other impo graph algos (some don't fit under larger umbrella) we haven't covered in past (or even variations of shortest path, etc.)
- 5) Week 10  $\Rightarrow$  Summary + Ongoing research + future trends

Spring session: Quantum computing

# Introduction

# Applications

---

- Professors to courses
- Employees to tasks
- Stable marriage problem (men to women)
- College admissions process
- Many other similar problem statements

# Stable marriage problem

— — —

- N men and N women
- Men and women have set of preferences
- Want to match the men and women in pairs

# Some vocabulary

---

- **Matching S** = set of pairs s.t. each member of M and each member of W appears in AT MOST 1 PAIR
- **Perfect matching S** = set of pairs s.t. Each member of M and each member of W appears in EXACTLY 1 PAIR
- **Stable matching S** = type of perfect matching with NO INSTABILITY (adding preferences or ranking)
- **Instability** = pair  $(m, w')$  is an instability when both  $m$  and  $w'$  prefer each other in their rankings but are not a pair in  $S$

— — —

An instability:  $m$  and  $w'$   
each prefer the other to  
their current partners.

**Figure 1.1** Perfect matching  $S$  with instability  $(m, w')$ .

Kleinberg & Tardos**

# Interesting things to think about

— — —

- Does there exist a stable matching for every bipartite graph?
- When there is a stable matching for a bipartite graph, can we efficiently construct one?

# Scenarios

---

In both of these scenarios  $\Rightarrow M = \{m, m'\}$  and  $W = \{w, w'\}$ .

Goal  $\Rightarrow$  Given following scenarios with preferences, construct STABLE matching

- 1) Scenario 1 - only 1 stable matching
  - a)  $m \Rightarrow \{w, w'\}$  AND  $m' \Rightarrow \{w, w'\}$
  - b)  $w \Rightarrow \{m, m'\}$  AND  $w' \Rightarrow \{m, m'\}$
- 2) Scenario 2 - 2 stable matching possibilities
  - a)  $m \Rightarrow \{w, w'\}$  AND  $m' \Rightarrow \{w', w\}$
  - b)  $w \Rightarrow \{m', m\}$  AND  $w' \Rightarrow \{m, m'\}$

# Gale-Shapley (GS) Algorithm

# Pseudocode

---

- Initialization stage: everyone is unmarried
- Unmarried man  $m$  chooses woman  $w$  who's highest on his list to propose to  $\Rightarrow$  not necessary that  $(m, w)$  is part of stable matching = engagement
  - Because woman may override and accept somebody's offer or she also may not have any other options
- Continue with next unmarried man
  - If  $w$  is free  $\Rightarrow$  engagement, else  $w$  checks if need to override previous engagement with new man by looking at her preference list
- Algorithm is over when engagements are COMPLETE and final

---

```
Initially all  $m \in M$  and  $w \in W$  are free
While there is a man  $m$  who is free and hasn't proposed to
every woman
    Choose such a man  $m$ 
    Let  $w$  be the highest-ranked woman in  $m$ 's preference list
    to whom  $m$  has not yet proposed
    If  $w$  is free then
         $(m, w)$  become engaged
    Else  $w$  is currently engaged to  $m'$ 
        If  $w$  prefers  $m'$  to  $m$  then
             $m$  remains free
        Else  $w$  prefers  $m$  to  $m'$ 
             $(m, w)$  become engaged
             $m'$  becomes free
        Endif
    Endif
Endwhile
Return the set  $S$  of engaged pairs
```

---

Kleinberg & Tardos**

# Algorithm Analysis

# Important lemmas

---

- 1) Woman  $w$  will remain engaged till the end ever since she's first engaged
  - a) Beginning  $\Rightarrow$  man proposes to her  $\Rightarrow$  she's engaged, later iterations  $w$  can decide whether to switch her partner or not
- 2) As time progresses, man  $m$  proposes to worse women on his list (in terms of his preference list)
  - a) Man  $m$  will always go with highest ranked one and when he can't go with highest, he will try proposing with ones who are lower ranked on his list

# More important lemmas

---

- 1) Gale-shapley algorithm will end in runtime proportional to  $n^2$  ( $n^2$  loops/iterations of while loop)
  - a) What step helps us get closer to termination?
  - b) Each iteration  $\Rightarrow$  man  $m$  proposes to a new woman  $w$  (once and only once)
    - i)  $n^2$  total possible pairs of men and women
    - ii) Max of  $n^2$  possible proposals so worst case is proportional to  $n^2$

# Proving S (result) is a PERFECT MATCHING

---

Perfect matching = NO FREE MAN. PROOF =

- 1) If  $m$  is free during anytime of the algo, he hasn't proposed to a woman  $w$ .
  - a) Assume by contradiction that  $m$  has proposed to every woman and he's still free. Then, all  $n$  women are engaged. This implies that there must be  $n$  men also engaged because of the pair property. Thus, we've proved the claim.
- 2) Result - set  $S$  - is a perfect matching
  - a) Let us assume algorithm ends with a free man  $m$ . But, we know that according to algorithm,  $m$  would have proposed to every woman to see if he can get engaged. This contradicts previous lemma, which states that there can't exist a free man who proposed to every woman since he hasn't proposed to a woman  $w$ .

# Proving $S$ results in a STABLE matching

— — —

TRY PROVING THIS ON YOUR OWN FIRST

USE PROOF BY CONTRADICTION (take actual case)
